Miscarriage: Why women need more time to grieve

Grief is common after miscarriage but it is not clear whether women who have miscarried are at greater risk of depression than women who have not.

Most studies about women’s mental health after miscarriage are based on very small numbers of women, or only include women who attend a hospital for their miscarriage.

This study used data from the Australian Longitudinal Study on Women’s Health (ALSWH) to explore the mental health of young women who had experienced early pregnancy loss.

Researchers used Information collected from 8000 young women in ALSWH through questionnaires to compare the mental health of women who had experienced a miscarriage to those who had not.

In-depth interviews were also conducted with nine women about their experience of miscarriage and ways of coping following their loss.

What did the research find?

Interviews with women who had experienced miscarriage uncovered a complex mixture of grief, guilt and anger, even years after the event.

However, the questionnaire data showed that women who had experienced miscarriages were not at greater risk of depression than women who had not experienced miscarriages.

Although emotional distress after miscarriage may continue for many women for some time, the difficult process of coping with feelings after a miscarriage is not a sign of mental health problems, but rather a sign of emotional strength and resilience, as they slowly learn to deal with their reactions to this upsetting life event.

How can you use this research?

It is important to distinguish between grief reactions and anxiety or depression following miscarriage.

Families and health professionals need to give women the time and opportunity to grieve following pregnancy loss, before considering treatment for depression or anxiety.
